Cutover timberland can be made most productive by planting pine seedlings. However, for best results, the project should be carefully planned and the site prepared before planting. One year after planting, seedling survival should be checked and competing undesirable hardwoods controlled.

Planning

Before timber is harvested, a professional forester should examine the property to determine which area should be cut and which areas should be retained for future volume growth. The forester can also assist with harvest planning. A private consulting forester should be contacted to assist with determining timber value and the best way to market the timber. After the timber is harvested, the forester should examine the area to determine what will be necessary to prepare the area for planting.

After harvesting is completed and if cost-share assistance is desired, the landowner must file an application for assistance and receive approval before the project begins. The Virginia Department of Forestry will accept applications for Reforestation of Timberland (RT) assistance starting in May each year. Often there are other cost-share programs available from other sources, and your local Department of Forestry personnel will have information on those programs.

Site Preparation

Preparing the site can be accomplished in several ways. Some methods are: (1) prescribed burning; (2) herbicide application, with or without prescribed burning; (3) bulldozing, and (4) drum chopping and prescribed burning.

In some cases, no site preparation is necessary. A VDOF forester can determine the best option for your situation.

- Prescribed burning to clean up logging debris can be successful on some cutover tracts. Prescribed burning is done between mid-May and mid-October.
- Herbicide application is usually done from May to September. Depending on the herbicide used and weather conditions, the tract can be burned three to eight weeks after herbicide application. Depending upon the site, burning may not be needed.
◆ Bulldozing, to pile logging debris, is usually done in the fall or winter months, but can be done any time of year.

◆ Drum chopping is a procedure to push over standing material and compacting it so the area can be prescribed burned. Drum chopping is accomplished with a bulldozer, pulling a rolling drum with blades. Drum chopping should be done between May and September. Depending upon weather conditions, the tract can be prescribed burned several weeks after the drum chopping has been completed.

Planting

During the fall or winter following site preparation, seedlings can be ordered from the Department of Forestry. During the winter or early spring, the Department of Forestry staff or a consulting forester can, at the landowner’s request, assist with securing a planting crew, obtaining seedlings and inspecting the planting. After the planting work is completed, the contractor will bill the landowner for the planting labor.

Some Department of Forestry services, such as planting coordination and site preparation, may require a fee. Contact your local forester regarding services that apply to your project.

If cost-share assistance has been approved for the project, payment will be made after the landowner has paid the contractor and Department of Forestry for expenses incurred.

Checking Survival

One year after the pine seedlings are planted, the tract should be examined for seedling survival and to what extent hardwood sprouts are competing with the planted seedlings.

Many tracts will need to have hardwood sprout competition controlled. The Virginia Department of Forestry can assist with coordination or may provide this service, for a fee, whereby the hardwood sprout competition will be sprayed and controlled with an herbicide.
